This environmental information handbook was prepared to assist both the non-technical reader (i.e., homeowner) and technical persons (such as researchers, policy analysts, and builders/designers) in understanding the current state of knowledge regarding combustion sources of indoor air pollution. Quantitative and descriptive data

addressing the emissions, indoor concentrations, factors influencing indoor concentrations, and health effects of combustion-generated pollutants are provided. In addition, a review of the models, controls, and standards applicable to indoor air pollution from combustion sources is presented. The emphasis is on the residential environment. The data presented here have

been compiled from government and privately-funded research results, conference proceedings, technical journals, and recent publications. It is intended to provide the technical reader with a comprehensive overview and reference source on the major indoor air quality aspects relating to indoor combustion activities, including tobacco smoking. In addition,

techniques for determining potential concentrations of pollutants in residential settings are presented. This is an update of a 1985 study documenting the state of knowledge of combustion-generated pollutants in the indoor environment. 191 refs., 51 figs., 71 tabs.

Excimer Laser Fragmentation Fluorescence Spectroscopy for Real-time Monitoring of Combustion

Generated Pollutants National Academies Press Energy is the issue of great importance at the present. Coal, the cheapest and the most abundant reserve fossil fuel, is currently one of the most widely used energy source globally and will continue to be in the foreseeable future. The use of coal has also posed many world-wide environmental challenges, including the control of	particulate matter, mercury, and trace metals, and carbon oxide (CO ₂) emissions. The rising of CO ₂ level in the atmosphere due to burning of fossil fuels is one of the major factors contributing to the global climate change. Capturing CO ₂ from coal combustion exhaust has been receiving significant attention; however, the volume fraction of CO ₂ in conventional coal	combustion system (with air) ranges only 13%-15%, making it difficult to cost-effectively design the systems. Oxy-coal combustion or O ₂ /CO ₂ recycled coal combustion is one of the promising techniques to overcome the limitation of low CO ₂ concentration in the exhaust. Before this technology can be employed, the effects of oxy-coal combustion on
---	---	--

the pollutants associated with coal combustion, including fine particle, gaseous mercury and heavy metal emissions, need to be established. In addition, the influences of oxy-coal combustion on the performance of the current pollution control technologies, such as an electrostatic precipitator (ESP), need to be addressed. This dissertation investigated two aspects of coal

combustion process: (1) pollutant formation, specifically submicrometer particles and mercury, and (2) pollutant control. The first part of dissertation addresses the impact of oxy-coal combustion on the formation submicrometer particles and the speciation of gaseous mercury. The second part focuses on the performance of two pollutant control technologies, including an ESP for capturing

submicrometer particles and nano-structured TiO₂ with UV irradiation for mercury capture. The findings presented here can be broadly divided into three parts. The first part reports the influence of oxy-coal combustion on submicrometer particle formation and capture using an ESP. The second part addresses the impacts of oxy-coal combustion on mercury speciation. The third part

investigates the performance of nano-structured sorbent for capturing mercury and controlling heavy metal emissions from combustion process. The findings presented here can be used as a guideline for proper operation and control of pollutants generated from both oxy-coal and conventional combustion systems.

Industrial Combustion Pollution

and Control
Springer
This book considers the pollutants formed by the combustion of solid biomass fuels. The availability and potential use of solid biofuels is first discussed because this is the key to the development of biomass as a source of energy. This is followed by details of the methods used for characterisation of biomass and their classification. The various steps in the combustion mechanisms

are given together with a compilation of the kinetic data. The chemical mechanisms for the formation of the pollutants: NO_x, smoke and unburned hydrocarbons, SO_x, Cl compounds, and particulate metal aerosols are given in detail. Combustion kinetics required for the application for design purposes are given. Examples are given of emission levels of a

range of different types of combustion equipment. Data is given of NO_x, particulates and other pollutant arising from combustion of different fuels in fixed bed combustion, fluidized bed combustion and pulverised biomass combustion and co-firing. Modeling methods including computational fluid dynamics for the various pollutants are outlined. The consequential issues arising from the wide scale use of

biomass and future trends are then discussed. In particular the role of carbon capture and storage in large biomass combustion plants is considered as well as the opportunity of reducing the concentration of atmospheric concentration of carbon dioxide. [A Preliminary Report from Rock Springs Site 12](#) Springer Science & Business Media The objective of this study is to compare

combustion pollutants produced from biogas &, their fossil fuel counterpart, natural gas to determine optimum combustion conditions. The analysis was broken up into pollutant classification, combustion model selection, and regression model selection. Pollutants are evaluated based on global warming potential, local air quality standards, and effective heat transfer in order to

determine which combustion conditions are preferable. The four pollutants that are considered are carbon dioxide (CO₂), nitrous oxide (N₂O), nitrogen oxide (NO_x), and carbon monoxide (CO). The combustion model utilized for this study was a Chemkin perfectly stirred reactor with kinetic pathways created by the CRECK Polimi Database. The Chemkin model was

chosen to replicate a boiler and would run combustion scenarios with varying amounts of heat extracted from the combustion chamber to control the combustion temperature. In order to rank the combustion outputs, a logistic regression was developed using the least toxic outcomes to make a threshold for the combustion processes. All this

information makes a strong framework to classify the data produced for the study and any additional data that are generated. The results of the study made it clear that there is no combustion condition in which all the pollutants can be minimized, mainly because the carbon monoxide levels rebound as the combustion temperature falls. However, the study did determine that reducing

the combustion temperature and the relative methane content of the fuel air mixture results in lower pollutant outputs. The relative methane contents effect on the combustion pollutants was determined by the fuel gases performing better as the biogas content was increased.

Combustion-generated Air Pollution
World Health Organization
Carbon

monoxide (CO) is a toxic air pollutant produced largely from vehicle emissions. Breathing CO at high concentrations leads to reduced oxygen transport by hemoglobin, which has health effects that include impaired reaction timing, headaches, lightheadedness, nausea, vomiting, weakness, clouding of consciousness, coma, and, at high enough concentrations

and long enough exposure, death. In recognition of those health effects, the U.S. Environmental Protection Agency (EPA), as directed by the Clean Air Act, established the health-based National Ambient Air Quality Standards (NAAQS) for CO in 1971. Most areas that were previously designated as "nonattainment" areas have come into compliance with the

NAAQS for CO, but some locations still have difficulty in attaining the CO standards. Those locations tend to have topographical or meteorological characteristics that exacerbate pollution. In view of the challenges posed for some areas to attain compliance with the NAAQS for CO, congress asked the National Research Council to investigate the problem of CO in areas with meteorological and topographical problems. This interim report deals specifically with Fairbanks, Alaska. Fairbanks was chosen as a case study because its meteorological and topographical characteristics make it susceptible to severe winter inversions that trap CO and other pollutants at ground level. *Interim Report* DIANE Publishing

Exposure to particulate matter (PM) air pollution is the world's largest environmental health risk accounting for millions of premature deaths and disability-adjusted life years annually. PM originates from natural and anthropogenic sources such as dust from soil, combustion engines, and forest fires, among many others. PM exposure is quantified by measuring its mass

concentration in air. This measurement alone does not identify the sources of PM exposure, which can inform effective mitigation strategies and allow for studying source-specific health effects. There are several options for source apportionment (e.g. GC-MS and X-ray fluorescence), but they are costly and time consuming to conduct. Alternative methods for source

apportionment using low-cost techniques would be beneficial to the study of air pollution and its health effects. In this dissertation, I develop a method for source apportionment of combustion generated PM using fluorescent Excitation Emission Matrix (EEM) fluorescent spectroscopy and machine learning. First, I collected PM samples from combustion sources of concern to human health in the

laboratory. I analyzed cyclohexane extracts of cigarette smoke, diesel exhaust and wood smoke by EEM fluorescent spectroscopy and using the World Health Organization's guideline for annual mean PM exposure of 10 [micro]g/m³ as a basis of comparison I show EEM is sensitive enough to detect combustion generated PM at levels well below those of concern to human health. Next, mixtures

of the same laboratory sources are analyzed using EEM. Combining measurements of the individual sources with those of mixtures, I apply several machine learning techniques and a simple linear model to perform source apportionment and identification from the mixtures and compare the results. A convolutional neural network (CNN) is found to have the best

performance of all methods investigated. I describe in detail the architecture and data augmentation approach used for the CNN. Finally, the EEM-Machine Learning approach is used for source apportionment of environmental samples. Results and filter samples from an exposure assessment panel study are used for this analysis. The samples were analyzed using X-ray fluorescence

and source apportionment was conducted using Positive Matrix Factorization. Filters, archived in a freezer, were extracted with cyclohexane and analyzed by EEM. The resulting EEM spectra and source contribution estimates from PMF were used as training data for the application of machine learning. A CNN with the same architecture as applied to the laboratory samples and

Principal Component Regression showed similar results in predicting contributions from combustion generated PM. These methods were able to reproduce the XRF-PMF results with R2 values as high as 0.84 for vegetative burning and 0.52 for traffic emissions.

Oxy-coal Combustion

CRC Press
This collection of notes was assembled as a supplement and guide to a five-day short course

presented at the University of California at Berkeley, September 22-26, 1969. The scope of subject matter, while limited to combustion as a source of air pollution, at the same time is intended to give the broadest possible exposure within that area. The spectrum is deliberately wide, ranging from fundamentals of combustion and combustion reactions through performance

of combustion systems and to legal and administrative control.

Contributors to this compendium and lecturers in the subject were solicited from academic and public organizations. Most of the authors are from the statewide University of California and the California Department of Public Health. Notable individuals with particular expertise, from other institutions, were also invited to

contribute. The choice of instructor in each case was based upon a desire to collect a cross-section of outstanding individuals, each highly qualified technically in his field. These notes reflect the freedom which each author was encouraged to follow in providing supplementary material for his lecture. The staff of Continuing Education in Engineering, Professor Thomas Hazlett and

Daphne Stern, deserve commendation for their effective and successful handling of the innumerable details which were encountered. Professors Robert Sawyer and Laurence Caretto are herewith gratefully acknowledged for their support in the seemingly uncountable tasks necessary to assemble the entity which is represented. *Sources and Control of Combustion Generated*

Pollutants
Generated by the Combustion of Solid Biomass Fuels
This book presents WHO guidelines for the protection of public health from risks due to a number of chemicals commonly

present in indoor air. The substances considered in this review, i.e. benzene, carbon monoxide, formaldehyde, naphthalene, nitrogen dioxide, polycyclic aromatic hydrocarbons (especially benzo[a]pyrene), radon, trichloroethylene and tetrachloroethylene, have indoor sources, are known in respect of their hazardousness to health and are often found indoors in

concentrations of health concern. The guidelines are targeted at public health professionals involved in preventing health risks of environmental exposures, as well as specialists and authorities involved in the design and use of buildings, indoor materials and products. They provide a scientific basis for legally enforceable standards. **Indoor Air Quality Environmental**

The United States and China are the top two energy consumers in the world. As a

consequence, they are also the top two emitters of numerous air pollutants which have local, regional, and global impacts. Urbanization has led to serious air pollution problems in U.S. and Chinese cities; although U.S. cities continues to face challenges, the lessons they have learned in managing energy use and air quality are relevant to the Chinese experience. This report

summarizes current trends, profiles two U.S. and two Chinese cities, and recommends key actions to enable each country to continue to improve urban air quality. **Combustion Generated Air Pollution** IntechOpen This book aims to strengthen the knowledge base dealing with Air Pollution. The book consists of 21 chapters dealing with Air Pollution and its effects in the fields of Health,

Environment, Economy and Agricultural Sources. It is divided into four sections. The first one deals with effect of air pollution on health and human body organs. The second section includes the Impact of air pollution on plants and agricultural sources and methods of resistance. The third section includes environmental changes, geographic and climatic conditions due to air

pollution. The fourth section includes case studies concerning of the impact of air pollution in the economy and development goals, such as, indoor air pollution in México, indoor air pollution and millennium development goals in Bangladesh, epidemiologic and economic impact of natural gas on indoor air pollution in Colombia and economic growth and air pollution in Iran during development

programs. In this book the authors explain the definition of air pollution, the most important pollutants and their different sources and effects on humans and various fields of life. The authors offer different solutions to the problems resulting from air pollution. *Particulate Air Pollutants Resulting from Combustion* National Academies Press

The research reported here is the product of several years' effort to

elucidate one aspect of the air-pollution problem of urban complexes, namely, the direct contribution of combustion to the complement of exotic organic chemicals in the outdoor atmospheric environment. Most attention has been paid to the complex carbonaceous particulates produced by incomplete combustion, although investigations into gaseous byproducts of combustion

also have been carried out to a limited extent. Much of the research has been reported in various publications that will be cited. Work by other investigators along converging lines has been copious; however, since this report is not intended as a review of studies in the field of combustion particulates, the many references to the subject are not necessarily included but

may be found in the original accounts from this laboratory. **Submicrometer Particle Formation, Mercury Speciation, and Their Capture** This book considers the pollutants formed by the combustion of solid biomass fuels. The availability and potential use of solid biofuels is first discussed because this is the key to the development of biomass as a source of energy. This is followed by details of the

Hazards of
Combustion
Products**

The indoor air quality of residential buildings was characterized to determine the types, rates of emissions, and fates of gaseous and particulate air pollutants from typical indoor combustion appliances. Measurements were conducted in occupied residential buildings and during controlled laboratory

experiments with combustion appliances. The SO₂, NO, NO₂, O₃, CO, and CO₂ concentrations and aerosol size distribution were determined on a continuous basis. Total and respirable-fraction particulate samples were collected on membrane filter media for analysis by x-ray fluorescence (XRFA), photoelectron spectroscopy (ESCA), proton activation analysis (PAA),

combustion, and wet-chemistry techniques for the determination of particulate elemental composition (S, N, C, etc.) and ionic species such as SO₄²⁻, NO₃⁻, and NH₄. Results of the study indicate that the concentrations of some gaseous and respirable particulate air pollutants in the indoor environment exceed those levels commonly found in the outdoor urban air

environment. Such findings may have a large impact on the future design of epidemiology studies, on energy conservation strategies for buildings, and on the need for more stringent control of air pollution from indoor combustion sources. An Investigation of Some Combustion-generated Pollutants A simulation model (also called a "macromodel") has been developed to

predict residential air pollutant concentration distributions for specified populations. The model inputs include the market penetration of pollution sources, pollution source characteristics (e.g., emission rates, source usage rates), building characteristics (e.g., house volume, air exchange rates), and meteorological parameters (e.g., outside temperature). Four geographically distinct

regions of the US have been modeled using Monte Carlo and deterministic simulation techniques. Single-source simulations were also conducted. The highest predicted CO and NO₂ residential concentrations were associated with the winter-time use of unvented gas and kerosene space heaters. The highest predicted respirable suspended particulate concentrations were

associated with indoor cigarette smoking and the winter-time use of non-airtight wood stoves, radiant kerosene heaters, convective unvented gas space heaters, and oil forced-air furnaces. Future field studies in this area should (1) fill information gaps identified in this report, and (2) collect information on the macromodel input parameters to properly interpret the results. It is

almost more important to measure the parameters that affect indoor concentration than it is to measure the concentrations themselves. Combustion-Generated Air Pollution Fires are a common source of exposure to smoke and a range of toxicologically active chemicals. Providing a complete overview of the subject, this book provides comprehensive and detailed information on

combustion processes, estimation of rate of production of combustion products, dispersion of these products and their effects on health. Beginning with a chapter discussing the chemistry of combustion and detailing the mechanisms of burning, how different materials ignite and the nature of combustion products, the book goes on to examine specific combustion products in

detail, the toxicity and carcinogenicity of the products, their dispersion and methods of monitoring. With diverse coverage edited and authored by recognised experts in the field, this book will provide an essential text for those working in toxicology, combustion science, public health and environmental research. *The Ongoing Challenge of Managing Carbon Monoxide Pollution in Fairbanks,*

Alaska
Incineration has been used widely for waste disposal, including household, hazardous, and medical waste--but there is increasing public concern over the benefits of combusting the waste versus the health risk from pollutants emitted during combustion. Waste Incineration and Public Health informs the emerging debate with the most up-to-date information available on incineration, pollution, and human health--along with expert conclusions and recommendations for further research and improvement of such areas as risk communication. The committee provides details on: Processes involved in incineration and how contaminants are released. Environmental dynamics of contaminants and routes of human exposure. Tools and approaches for assessing possible human health effects. Scientific concerns pertinent to future regulatory actions. The book also examines some of the social, psychological, and economic factors that affect the communities where incineration takes place and addresses the problem of uncertainty and variation in predicting the health effects of incineration

processes.
